ABSTRACT

Nowadays, the introduction of home virtual assistants like Alexa Echo or Google Home became a practice, just considering that over 27% of families owns one.

It's obvious that those devices simplified the life by creating a smart house with few money; but what's the impact these devices have on people privacy? There are a lot of cases in the United States in which the judge asked to Amazon to provide the recording done by the Echo in order to find helpful evidences for the case; so, the question is: "It's possible to prevent the sending of sensible informations to the servers when the weak word is not pronounced?"

In this project we will profile each packet exchanged between the Alexa Echo and the Server in order to classify the nature of the packets and consequentially we will use a machine learning model to discover when the Echo is sending an inappropriate packet.

KEYWORDS

data analytics, alexa, packets profiling

1 INTRODUCTION

The evolution of smart devices over last years has increased exponentially and the introduction of these devices within the house is progressively growing. The major problem related to these devices is that usually the privacy is not considered, although there are a lot of regulations (just see the GDPR) that describe how the user data have to be stored and who can access to these data. Starting from these two points I decided to understand what happens within the context of smart assistance device such as Alexa Echo. Reading on the Amazon Alexa website it's clear how and when they send data to the Amazon Cloud, but in opposition we have some cases in which the recording done by the Echo have been used during the processes in order to extract some evidence. In order to clarify this aspect and the role of the smart assistance devices I decided to analyze the outgoing traffic from the device and classify it by considering the environmental conditions. The first phase of this analysis consist in understand which kind of packets are sent from the device in order to create a complete dataset of packets sent by the device; during the second phase I try to understand if exist a pattern that identify the packets that souldn't be sent to the Cloud by creating a machine learning model able to identify them.

2 STATE OF ART

During the last years different research have been done, related to different aspects of the security and privacy within the IoT context. F. Z. Berrehili and A. Belmekki [1] have done a study on the Privacy

Preservation in the IoT context that shows all the risks directly related to the architecture; in particular, it underlines the need to always guarantee the anonymization of sensible data by hiding the correlation between the data itself and the person who produced these data (that is also one of the principle of GDPR). Despite these studies, there is an huge percentage of devices that do not consider as serious all the aspects related to the privacy, in particular J. Liu and W. Sun [2] show different attacks againit werables devices at different levels of the ISO/OSI stack and considering different aspects of privacy and security like data integrity, authentication, authroization, etc. The study shows a lot of attacks aim at sniff the packets during the communication in order to collect sensible informations; this seems to be caused from the problem related to the poor encryption mechanisms implemented into the smart devices.

3 ALEXA ARCHITECTURE & SECURITY

The Alexa architecture isn't really easy to explain, we will resume just the keypoint in order to better understand the main functionalities for our purpose.

- (1) Alexa is always in listening waiting for the wake word to be pronounced to start the recording of the voice;
- (2) From the weak word, till the end of commands, Alexa will record the speech and partially sends it to Alexa Voice Service, that can be considered as the brain of Alexa;
- (3) Alexa Voice Service will process the audio using Natural Language Processing and Natural Language Understanding in order to retrieve a response for the given request.
 - (a) Natural Language Processing (NLP) improve the Word Segmentation that separate a chunk of continuous text into separate words.
 - (b) Natural Language Understanding (NLU) is a subtopic of NLP and uses the AI to map text to the meaning[3] in order to understand the speech and the request.
- (4) Depending on the sent command, the Voice Service will take an action (turn on the light) or send the information back to the device and Alexa may speech.

All the communications between the Echo and the Server are secured by using an SSL/TLS encryption schema. In particular, the Echo looks for an available Amazon Server each 3 minutes and then establish a connection (by following the SSL Handshake). Once the communication has been initialized it starts to send different packets of different size always encrypted; clearly, these packets may contains both authorized and unauthorized data. It's important to

underline that all the recordings are available on the Amazon platform and can be reproduced and deleted whenever the user wants only by accessing to the platform and this guarantee more transparency to the user that can directly handle all the recordings. The point is that here we found only the recordings done by the Echo in an authorized way (when the wake word it's been pronounced), but this doesn't imply that some other recordings can exist and be stored in hidden way.

4 PACKETS ANALYSIS

In order to create a good dataset we will classify the packets sent by the Echo. In particular is possible to classify the type of packet by looking at flags, packet size and protocol used. There are different types of packet that will later be included in the dataset as classes:

- (1) **handshake**: At the beginning of each new SSL/TLS communication between the Echo and the Server there are different packets exchanged in order to establish a secure communication. These packets can be easily identified by the protocol used for the communication (TLS) and by checking the flags related to the content of the message, in particular, the possible flags are:
 - (a) Change Cipher (20).
 - (b) Server Hello - Show Certificate - Encrypted Message (21).
 - (c) Alert (22).
- (2) **syn**: Packets with fixed length are sent from the device in a fixed interval, seems that them are used to synchronize the Echo to the Server.
- (3) **ack**: These are the classical packets used to confirm that the received packets are valid and successfully received.
- (4) **retransmit**: These packets are used to retransmit the data that didn't received an ack, usually this happens when the Echo try to communicate with other Amazon devices (Fire Stick for ex.) but doesn't receive response.
- (5) **app_data**: These packets are relative to the normal communication of the Echo and can be easily recognized since the communication happens over TLS/SSL protocol and by checking the flag of the considered packet that is equal to 23. In particular, we will include in this class all the communication packets that include also recording of voice occurred during the conversation between the Echo and the final customer.
- (6) **not_relevant**: We will include in this category all packets that don't match any of the other categories, and are not relevant for our study.

It's import to underline that the packets classified as `app_data` may include both authorized and not authorized packets. The unauthorized packets include all those packets sent in a context in which no application date should be sent to the Server by considering the environmental variables (no wake word pronounced) and hardware aspects (microphone muted by pressing the relative button); for this reason is important to introduce some classes related to these aspects. The aim is to distinguish three kind of packets:

- **not_justified**: packets sent to the Server in a context in which the Echo is unable to send these data by considering the hardware aspects.

- **justified**: packets sent to the Server without any interaction between the Echo and the Customer, but the Echo is able to listen.
- **expected**: packets sent to the Server since an interaction between the Echo and the Customer happened.

Clearly, the only allowed packets are those classified as "Expected".

4.1 Consideration on packet analysis

It's important to do some consideration over the analysis / collection phase just described, in fact there are a lot of behavioural pattern that the Echo follow to perform some actions:

- As introduced in the previous section there are some kind of packets that always follow the same schema in a given interval. These packets may be sent to guarantee the synchronization with the Amazon Alexa application and with the Amazon servers. There are two possible synchronization packets:
 - (1) A packet of 100 byte is sent each 30 seconds (30002 milliseconds)
 - (2) A packet of 99 byte is sent each 90 seconds (90820 milliseconds)
- The communication always happens using SSL/TLS, so it's impossible to decrypt the content of these message and confirm that is securely a synchronization packet.
- Music stream pattern is dependent on music service used; a stream with Amazon Music always uses a secure connection by using TLS.

Figure 3: Echo when the disable microphone button has been pressed.

- (2) **No wake word pronounced:** when the device is able to listen the voice but shouldn't send to the Server any packets of application data.
- (3) **Normal stream of data:** when a communication happens. It may include different questions or requests, for example:
 - (a) How is the weather today?
 - (b) When does Liverpool play?
 - (c) Add milk to the shopping list.
 - (d) How much is $20 + 20$?
 All these questions or requests expect a response from the Server, so a huge amount of ack will be sent from the device.
- (4) **Streaming:** when the user request for a song and the Echo start to stream it; also in this case a lot of ack packets are sent from the device as response to the fragment of the item to stream (a song for example).

5.1 Features

As introduced in the previous section it's important to collect features related to both hardware and software aspects; let's see in detail which are the considered features with the related meaning:

- (1) **date:** the date in which the packet has been collected, in the format YYYY-MM-DD hh:mm:ss.ms;
- (2) **length:** the length of the packet, it includes just the payload (in case of ack packet it's equal to zero);
- (3) **dstip:** the destination ip, collected to analyze the owner of the server to which the packet is directed;
- (4) **dstport:** the destination port;
- (5) **highest_layer:** the protocol used, in order to parse the protocol into an integer we will use the following mapping:
 - 0 - SSL
 - 1 - TCP
 - 2 - DATA
 - 3 - HTTP
 Notice that all the packets that use other protocol are discarded since they have no meaning for our purpose;
- (6) **delta:** the time occurred from the previous packet of the same stream;
- (7) **ack_flag:** the acknowledge flag; it is equal to 1 if the packet contains an ack;

- (8) **microphone:** the status of the microphone, it is equal to 1 if the microphone is active, 0 otherwise;
- (9) **content_type:** the type of content sent, it is valorized only if the packet is sent over SSL;
- (10) **synchronized:** status of synchronization of the device, it is equal to 1 if the Echo has been previously associated to an account, 0 otherwise.

Since we want to map every kind of packet in a class, 8 classes have been declared: handshake, syn, ack, retransmit, not_relevant, justified, not_justified and expected.

5.2 Dataset merging

Since we have collected packets into four different contexts is necessary to merge together all these dataset before to apply any kind of manipulation on data. In particular during the collection phase we have collected 5436 packets when the microphone has been disabled, 39793 packets when the music was streaming (independently by the service used), 9374 packets when no wake word has been pronounced and 8027 packets during a normal conversation with the Echo. Clearly, a first overview on these numbers may start thinking that it's totally unbalanced; but we should remember that during the streaming of contents there is an huge amount of ack packets that can be potentially discarded; we will see this operation in the following subsection.

5.3 Avoid NaN values

During a first overview on collected packets it's been noticed that there are some packets in which the content_type feature is set to NaN. This problem has been caused by the collecting phase; in fact,

Features and n° of NaN values	
date	0
length	0
dstip	0
dstport	0
highest_layer	0
delta	0
ack_flag	0
microphone	0
content_type	51563
synchronized	0
class	0

Figure 4: NaN values related to the content_type feature.

as already introduced in the subsection 5.1, this feature is valorized only when we capture an SSL packet, otherwise it is set to NaN. In order to fix this problem, all the existing NaN values for the content_type feature has been set to 0.0.

5.4 Not relevant features

The dataset contains also instance-specific information, like date and destination ip of the packets. Since these values cannot be used

during the training phase (otherwise the model will use these values to predict the class of the packets) we need to completely discard these features by deleting the column from the dataset.

5.5 Dataset analysis

After removed the NaN values and the not relevant features is important to analyze the collected packets in order to understand if them can be already used or exist some other correction that must be applied before the training. The analysis is divided into target and features analysis.

5.5.1 Target class analysis. Let's start the analysis of the target class by understanding how many packets have been collected for each class.

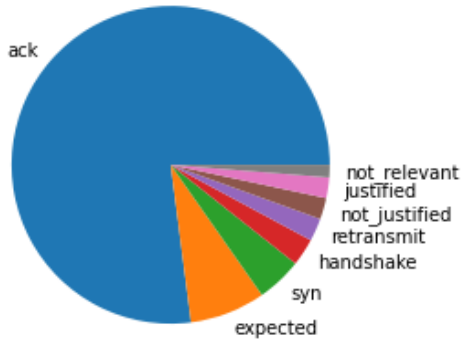

Figure 5: Distribution of target classes.

It's clear the presence of too many ack packets respect to the other classes; as said before this is caused by the streaming context; in fact when a song is streaming, the Echo will send a lot of ack corresponding to each fraction of the song that has been received from the Echo. The total amount of ack packets is 48252, respect to: 4813 for expected; 2888 for syn; 1751 for handshake; 1457 for retransmit; 1361 for not_justified; 1316 for justified and 792 for not_relevant. Translated into percentage, the number of ack packets correspond to the 77% over the total. In order to make more balanced the overall dataset we will consider just the 5% of these packets, that is equal to 2413. The deletion of the row is random.

Figure 6: Distribution of target classes after 95% ack packets delete.

5.5.2 Features analysis. After guarantee a good distribution for the target classes, we start our analysis on the features. Let's see the distribution of length of packets in correlation with the target classes.

Figure 7: Distribution of length in correlation with target classes.

It's clear that synchronization and acknowledge packets have a short length compared with the others; in fact these packets have small data within them, a simple text or just a flag. Instead, application data packets such as not justified, justified and expected packets have a variable longer length; in fact these packets are usually used to send voice recording for example. Another important consideration is that there is a small difference between the expected and the justified / not justified packets; the first ones usually have a smaller length, while the others have similar behaviour between each other but the average of length is much higher respect to the expected ones.

Anyway we are not worried about the difficulty for the classifier to distinguish the justified ones from the not justified ones; in fact we know that any justified packet exists with the microphone off (by the assumption done during the collection phase). Notice that this behaviour is not exclusive each other, in fact some not justified packet may exists when the microphone is on and nothing is happening in the external environment.

```
Not justified packets with microphone on: 886
Justified packets with microphone on: 1316
```

```
Not justified packets with microphone off: 475
Justified packets with microphone off: 0
```

Figure 8: Distribution of justified and not justified packets in correlation with microphone on/off.

Till now, we did not talk about the synchronized feature; this feature figure out the state of synchronization of the device (if it is associated with an Amazon account or not). The problem here is that an Echo cannot work if it is not synchronized with any account,

in fact if we plot a pie chart of the distribution of this feature we can easily see that all the captured packets have been captured when the device was synchronized.

Synchronized: 16791
Not Synchronized: 0

Figure 9: Distribution of synchronized packets.

For this reason we have to delete also this feature (it isn't relevant for our purpose).

One of the last analysis regards the distribution of ack flag; in fact this flag seems quite always set to 1 (usually a communication packets may contains also an acknowledge of the previous recieved packet) but we decide to maintain this feature since there is a 10% of packets in which this flag is set to 0, so it is useful for the training.

Ack flag: 15334
No ack flag: 1457

Figure 10: Distribution of ack packets.

Last analysis regard the distribution of highest_layer feature. Here we have a lot of SSL packets because this is the major protocol used for the communication between the Echo and the Server
