ABSTRACT

Nowadays, the introduction of home virtual assistants like Alexa Echo or Google Home became a practice, just considering that over 27% of families owns one.

It's obvious that those devices simplified the life by creating a smart house with few money; but what's the impact these devices have on people privacy? There are a lot of cases in the United States in which the judge asked to Amazon to provide the recording done by the Echo Dot in order to find helpful evidences for the case; so, the question is: "It's possible to prevent the sending of sensible informations to the servers when the weak word is not pronounced?"

In this project we will profile each packet exchanged between the Alexa Echo and the Server in order to classify the nature of the packets and consequently we will use a machine learning model to discover when the Echo Dot is sending an inappropriate packet.

KEYWORDS

data analytics, alexa, packets profiling

1 INTRODUCTION

TODD

2 ALEXA ARCHITECTURE & SECURITY

The Alexa architecture isn't really easy to explain, we will resume just the keypoint in order to better understand the main functionalities for our purpose.

- (1) Alexa is always in listening waiting for the wake word to be pronounced to start the recording of the voice;
- (2) From the weak word, till the end of commands, Alexa will record the speech and partially sends it to Alexa Voice Service, that can be considered as the brain of Alexa;
- (3) Alexa Voice Service will process the audio using Natural Language Processing and Natural Language Understanding in order to retrieve a response for the given request.
 - (a) Natural Language Processing (NLP) improve the Word Segmentation that separate a chunk of continuous text into separate words.
 - (b) Natural Language Understanding (NLU) is a subtopic of NLP and uses the AI to map text to the meaning[?] in order to understand the speech and the request.
- (4) Depending on the sent command, the Voice Service will take an action (turn on the light) or send the information back to the device and Alexa may speech.

4 ALEXA FLOW OF COMMUNICATION

Describe here the entire flow of communication

5 PACKETS ANALYSIS

In order to create a good dataset we will classify the packets sent by the Echo. In particular is possible to classify the type of packet by looking at flags, packet size and protocol used. There are different types of packet that will later be included in the dataset as classes:

- (1) **handshake**: At the beginning of each new SSL/TLS communication between the Echo and the Server there are different packets exchanged in order to establish a secure communication. These packets can be easily identified by the protocol used for the communication (TLS) and by checking the flags related to the content of the message, in particular, the possible flags are:
 - (a) Change Cipher (20).
 - (b) Server Hello - Show Certificate - Encrypted Message (21).
 - (c) Alert (22).Echo changes communication Server very frequently, about each 2 minutes.
- (2) **syn**: Two packets with fixed length are sent from the device in a fixed interval, for this reason we believe that these are synchronization packets. These packets may be sent to guarantee the synchronization with the Amazon Alexa application and with the Amazon servers. There are two possible synchronization packets:
 - (a) A packet of 100 byte is sent each 30 seconds (30002 milliseconds)
 - (b) A packet of 99 byte is sent each 90 seconds (90820 milliseconds)The communication always happens using SSL/TLS, so it's impossible to decrypt the content of these message and confirm that is securely a synchronization packet.
- (3) **ack**: These are the classical packets used to confirm that the received packets are valid and successfully received.
- (4) **retransmit**: These packets are used to retransmit the data that didn't received an ack, usually this happens when the Echo try to communicate with other Amazon devices (Fire Stick for ex.) but doesn't receive response.
- (5) **app_data**: These packets are relative to the normal communication of the Echo and can be easily recognized since the communication happens over TLS/SSL protocol and by checking the flag of the considered packet that is equal to 23.

In particular, we will include in this class all the communication packets that include also recording of voice occurred during the conversation between the Echo and the final customer.

- (6) **not_relevant**: We will include in this category all packets that don't match any of the other categories, and are not relevant for our study.

It's import to underline that the packets classified as `app_data` may include both legitimate or illegitimate packets. The illegitimate packets include all those packets sent in a context in which no application data should be sent to the Server by considering the environmental variables (no wake word pronounced) and hardware aspects (microphone muted by pressing the relative button); for this reason is important to introduce some features related to these aspects. The aim is to distinguish three kind of packets:

- **not_justified**: packets sent to the Server in a context in which the Echo is unable to send these data by considering the hardware aspects.
- **justified**: packets sent to the Server without any interaction between the Echo and the Customer, but the Echo is able to record.
- **expected**: packets sent to the Server since an interaction between the Echo and the Customer happened.

Clearly, the only allowed packets are those classified as "Expected".

6 DATASET

In order to create a valid and well-distributed dataset we analyzed the behavior of the Echo Dot in different context, in particular by considering different cases:

- (1) **Microphone mute**: when the hardware button is pressed and the device should be unable to send application data to the server.

Figure 1: Echo Dot when the disable microphone button has been pressed.

- (2) **No wake word pronounced**: when the device is able to listen the voice but shouldn't send to the Server any packets of application data.

- (3) **Normal stream of data**: when a communication happens.

It may include different questions or requests, for example:

- How is the weather today?
- When does Liverpool play?
- Add water to the cart.

All these questions or requests expect a response from the Server, so a huge amount of ack will be sent from the device.

- (4) **Stream of data**: when the user request for a song and the Echo Dot start to stream it.
